

- Even small software systems need to use tools to control builds.
- Many, many tools available
- Tools popular with developers often changing, and specific to platform/language.
- We'll look at a classic tool **make** which is still widely used e.g. Linux kernel
- If you want current alternative: cmake + ninja
- But you should know **make**

make allows you to

- document intra-module dependencies
- automatically track of changes

make works from a file called Makefile (or makefile)

A Makefile contains a sequence of rules like:

```
target : source1 source2 ...
      commands to create target from sources
```

**Beware:** each command is preceded by a single **tab** character.

Take care using cut-and-paste with Makefiles

1

2

## Dependencies

## Example Multi-module C Program

The **make** command is based on the notion of *dependencies*.

Each rule in a Makefile describes:

- dependencies between each target and its sources
- commands to build the target from its sources

Make decides that a target needs to be rebuilt if

- it is older than any of its sources (based on file modification times)

### main.c

```
#include <stdio.h>
#include "world.h"
#include "graphics.h"

int main(void)
{
    ...
    drawPlayer(p);
    fade(...);
}
```

### world.h

```
typedef ... Ob;
typedef ... Pl;
extern addObject(Ob);
extern removeObject(Ob);
extern movePlayer(Pl);
```

### world.c

```
#include <stdlib.h>

addObject(...)
{ ... }

removeObject(...)
{ ... }

movePlayer(...)
{ ... }
```

### graphics.h

```
extern drawObject(Ob);
extern drawPlayer(Pl);
extern spin(...);
```

### graphics.c

```
#include <stdio.h>
#include "world.h"

drawObject(Ob o);
{ ... }

drawPlayer(Pl p)
{ ... }

fade(...)
{ ... }
```

Building with incremental compilation:

```
$ gcc -c -g -Wall world.c
$ gcc -c -g -Wall graphics.c
$ gcc -c -g -Wall main.c
$ gcc -Wall -o game main.o world.o graphics.o
```

3

4

For systems like Linux kernel with 50,000 files building is either

- inefficient (recompile everything after any change)
- error-prone (recompile just what's changed + dependents)
  - module relationships easy to overlook  
(e.g. graphics.c depends on a typedef in world.h)
  - you may not know when a module changes  
(e.g. you work on graphics.c, others work on world.c)

A Makefile for the earlier example program:

```
game : main.o graphics.o world.o
      gcc -Wall -o game main.o graphics.o world.o

main.o : main.c graphics.h world.h
      gcc -c main.c

graphics.o : graphics.c world.h
      gcc -c -g -Wall graphics.c

world.o : world.c
      gcc -c -g -Wall world.c
```

5

6

## Example Makefile #1

## How make Works

Easily parsed in Perl:

```
open my $makefile, '<', $file or die;
while (<$makefile>) {
    my ($target, $depends) = /(\S+)\s*:\s*(.*)/
    or next;
    $first_target = $target if !defined $first_target;
    $depends{$target} = $depends;
    while (<$makefile>) {
        last if !/^\\t/;
        $build_cmd{$target} .= $_;
    }
}
```

The make command behaves as:

```
make(target, sources, command):
    # Stage 1
    FOR each S in sources DO
        rebuild S if it needs rebuilding
    END
    # Stage 2
    IF (no sources OR
        any source is newer than target) THEN
        run command to rebuild target
    END
```

7

8

```

my ($target) = @_;
my $build_cmd = $build_cmd{$target};
die "*** No rule to make target $target\n" if
    !$build_cmd && !-e $target;
return if !$build_cmd;
my $target_build_needed = ! -e $target;
foreach $dep (split /\s+/, $depends{$target}) {
    build $dep;
    $target_build_needed ||= -M $target > -M $dep;
}
return if !$target_build_needed;
print $build_cmd;
system $build_cmd;

```

```

# string-valued variables/macros
CC = gcc
CFLAGS = -g
LDFLAGS = -lm
BINS = main.o graphics.o world.o

# implicit commands, determined by suffix
main.o      : main.c graphics.h world.h
graphics.o  : graphics.c world.h
world.o     : world.c

# pseudo-targets
clean :
    rm -f game main.o graphics.o world.o
    # or ... rm -f game $(BINS)

```

9

10

```

# multiple targets with same sources
stats1 stats2 : data1 data2 data3
    perl analyse1.pl data1 data2 data3 > stats1
    perl analyse2.pl data1 data2 data3 > stats2

# creating subsystems via make
parser:
    cd parser && $(MAKE)
    # assumes parser directory has own Makefile

```

```

open MAKEFILE, $file or die;
while (<MAKEFILE>) {
    s/#.*//;
    s/\$((\w+)\)/$variable{$1}||'/eg;
    if (/^\s*(\w+)\s*=\s*(.*)$/) {
        $variable{$1} = $2;
        next;
    }
    my ($target, $depends) = /(\S+)\s*:\s*(.*)/ or next;
    $first_target = $target if !defined $first_target;
    $depends{$target} = $depends;
    while (<MAKEFILE>) {
        s/\$((\w+)\)/$variable{$1}||'/eg;
        last if !/^\t/;
        $build_cmd{$target} .= $_;
    }
}

```

11

12

If `make` arguments are targets, build just those targets:

```
$ make world.o
$ make clean
```

If no args, build first target in the Makefile.

The `-n` option instructs `make`

- to tell what it would do to create targets
- but don't execute any of the commands

13

```
$makefile_name = "Makefile";
if (@ARGV >= 2 && $ARGV[0] eq "-f") {
    shift @ARGV;
    $makefile_name = shift @ARGV;
}
parse_makefile $makefile_name;
push @ARGV, $first_target if !@ARGV;
build $_ foreach @ARGV;
```

14

## Example Makefile #2

Sample Makefile for a simple compiler:

```
CC      = gcc
CFLAGS  = -Wall -g
OBJS     = main.o lex.o parse.o codegen.o

mycc : $(OBJS)
        $(CC) -o mycc $(OBJS)

main.o : main.c mycc.h lex.h parse.h codegen.h
        $(CC) $(CFLAGS) -c main.c

lex.o : lex.c mycc.h lex.h
        $(CC) $(CFLAGS) -c lex.c

parse.o : parse.c mycc.h parse.h lex.h
codegen.o : codegen.h mycc.h codegen.h parse.h
```

15

## Automatic Variables

To simplify writing rules, `make` provides some special variables

`$@` full name of target

`$*` stem of the target

`^` full name of all dependencies

`$?` full names of newer dependencies

`$<` full name of first dependency

Examples:

```
lex.o : lex.c mycc.h lex.h
        $(CC) $(CFLAGS) -c $.c -o $@
        # or ... $(CC) $(CFLAGS) -c $< -o $@

# update a library archive
lib.a: foo.o bar.o lose.o win.o
        ar r lib.a $?
```

16

```
my %builtin;  
$builtin{'@'} = $target;  
($builtin{'*'} = $target) =~ s/\.[^\.]*$//;  
$builtin{'^'} = $depends{$target};  
($builtin{'<'} = $depends{$target}) =~ s/\s.*//;  
$build_command =~ s/\$([@*^<])/$builtin{$1}||''/eg;
```
